(some material taken or adapted from slides by Hinrich Schutze)

Status

- Are you comfortable with your data?
- Are you comfortable with your research questions?
- Are your comfortable with the feature space you want to explore?
- Evaluation metrics?
- Compare models?
- We need to start thinking about presentation slots.
- Changing due date from the 10th Dec to 7th Dec.
- HW3 will be out tomorrow.

Clustering objective

- Grouping documents or instances into subsets or clusters
- Documents in the same cluster should be similar
- Documents in different clusters should be dissimilar
- A common form of unsupervised learning
- Unsupervised = no human-produced labels
- The goal is to discover structure from the data

Clustering vs. Classification

Classification:

- the input to the system is a set of labeled data
- the algorithm learns a model for predicting the label on new examples

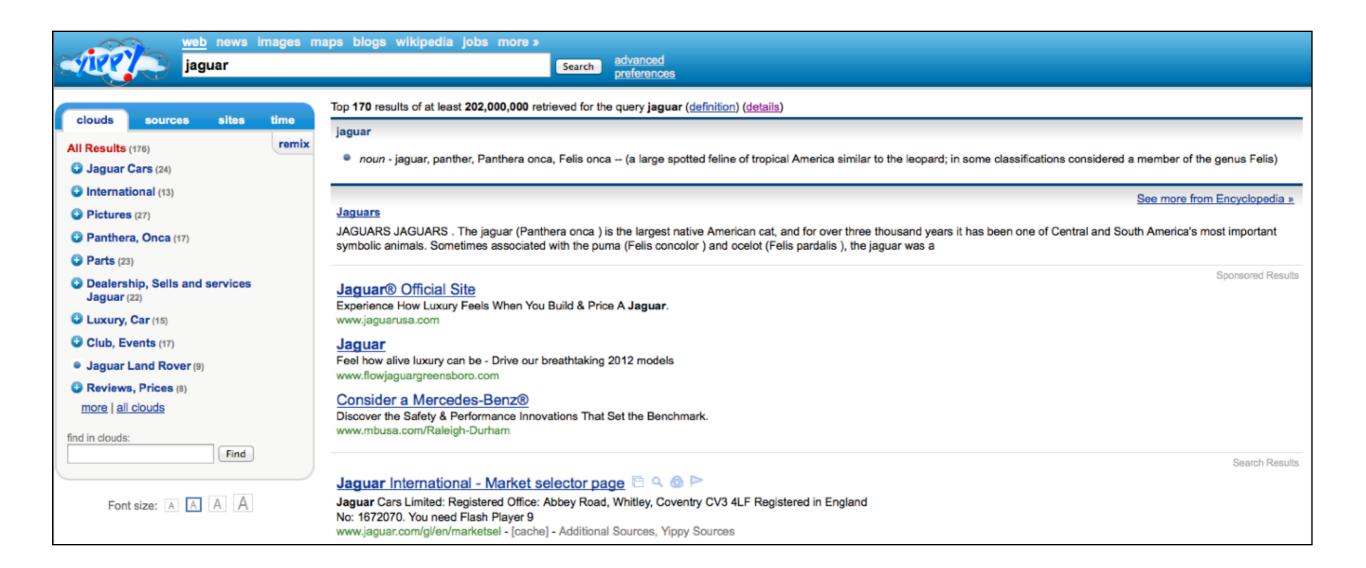

Clustering:

- the input to the system is a set of unlabeled data
- the algorithm infers the labels from the data and assigns a label to each input instance

Clustering applications

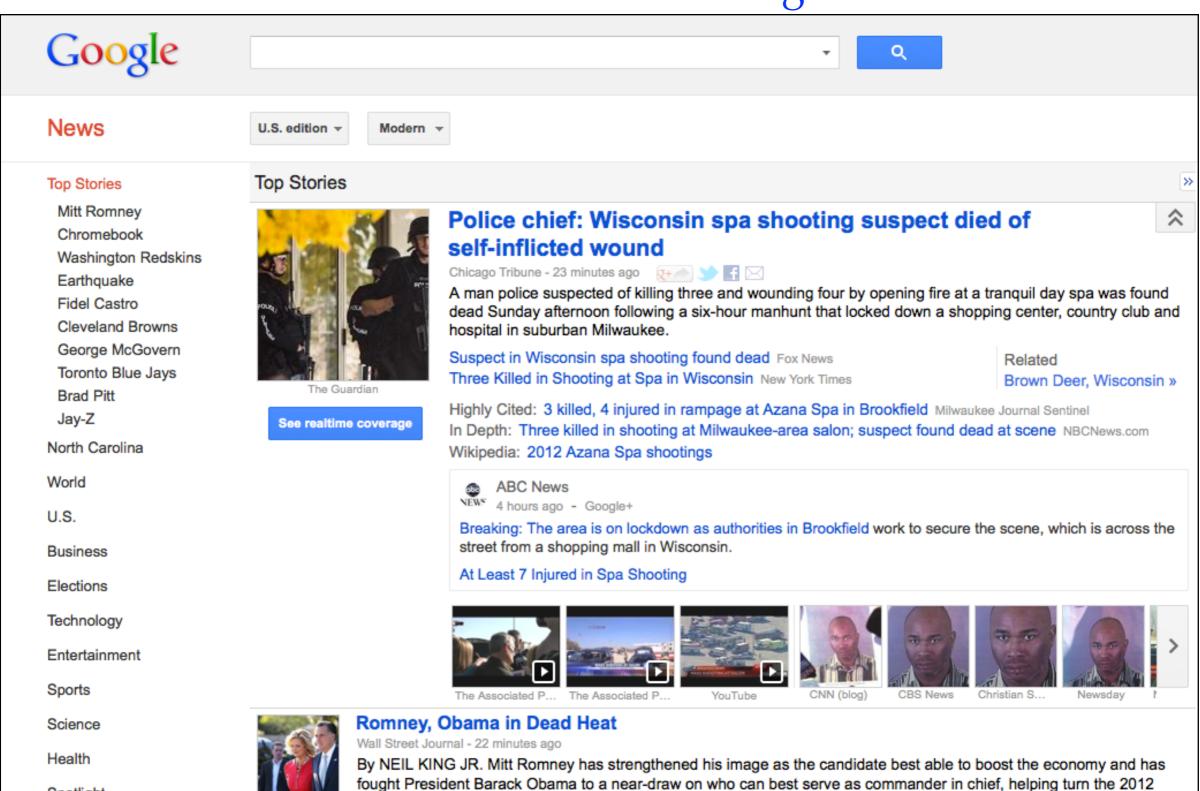

- Search engine results clustering: grouping search engine results by topic
 - the user can identify the relevant clusters and ignore the non-relevant ones
- Collection clustering: grouping documents by topic to support navigation and exploration
- Data analytics: grouping instances to identify popular trends (big clusters) and outliers (small clusters)

Clustering Applications search engine results clustering

Clustering objective

- Grouping documents or instances into subsets or clusters
- Documents within a the same cluster should be similar
- Documents from different clusters should be dissimilar

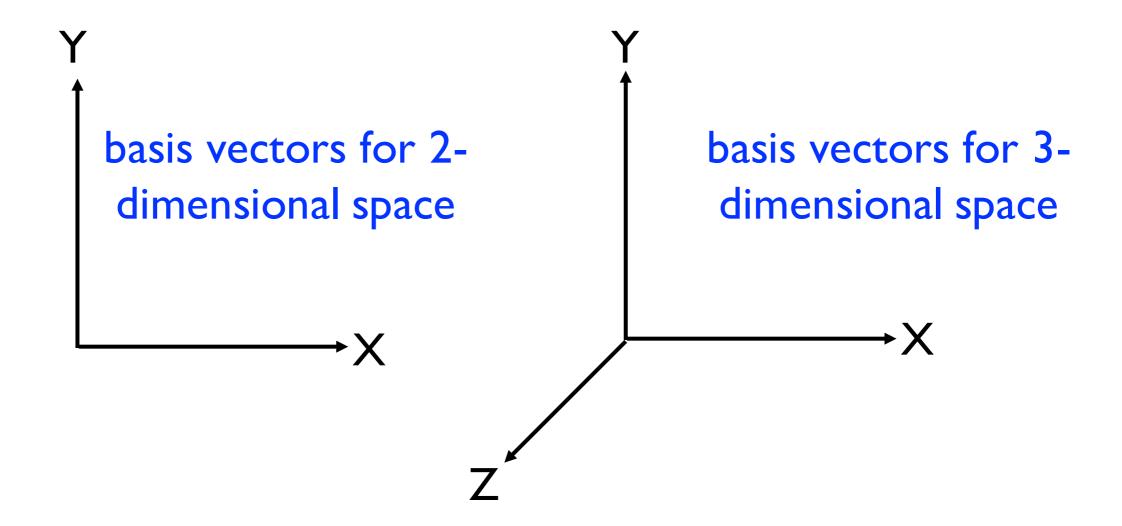

Clustering basics

 What does it mean for documents to be "similar" or "dissimilar"?

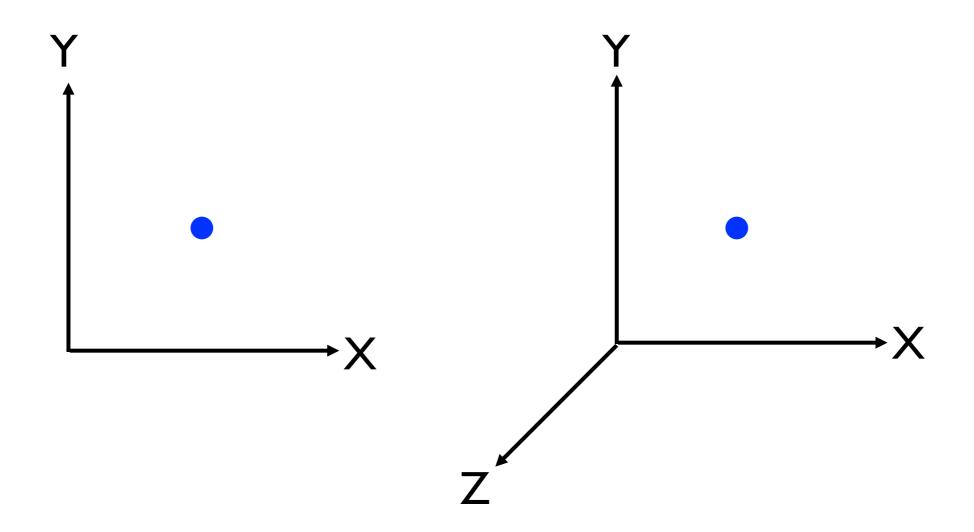

Clustering basics

- What does it mean for documents to be similar or dissimilar?
- We need a computational way of modeling similarity
- One solution: model similarity using distance in a vector space representation of the collection or dataset
 - small distance = high similarity
 - long distance = low similarity

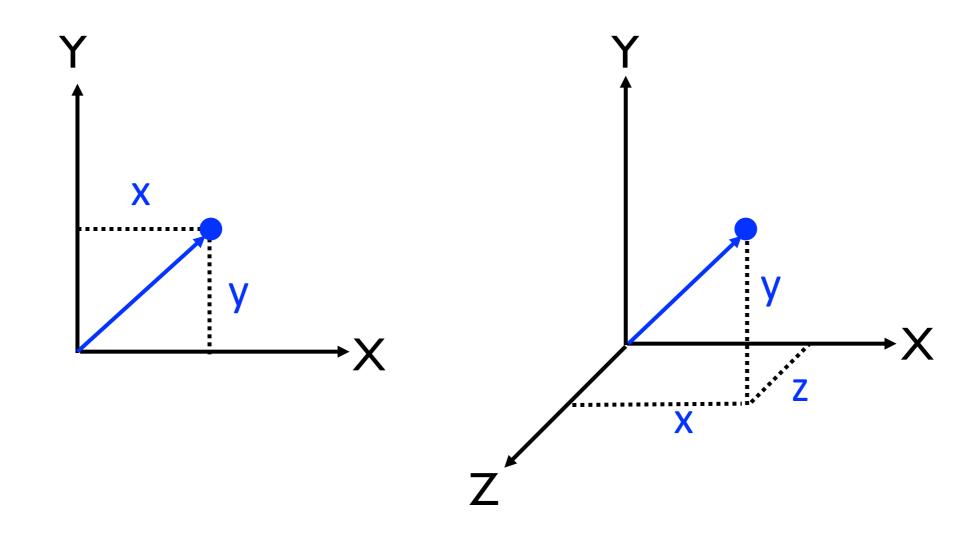

- A vector space is defined by a set of <u>linearly independent</u> basis vectors
- The basis vectors correspond to the dimensions or directions of the vector space

A vector is a point in a vector space

- A 2-dimensional vector can be written as [x,y]
- A 3-dimensional vector can be written as [x,y,z]

review

• Similarity = Euclidean Distance:

$$D(x,y) = \sqrt{\left(\sum_{i=1}^{|\mathcal{V}|} (x_i - y_i)^2\right)}$$

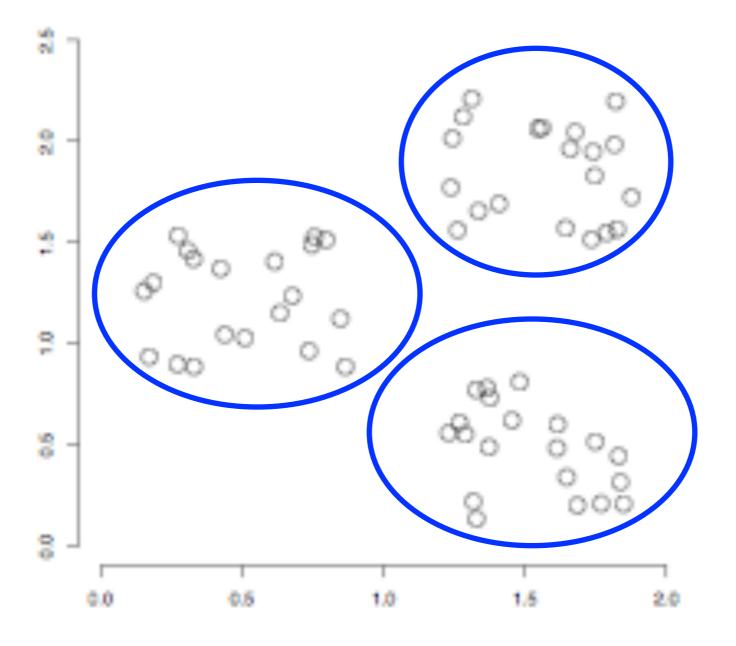

review

 What would we expect a clustering algorithm to do with this dataset?

 What would we expect a clustering algorithm to do with this dataset?

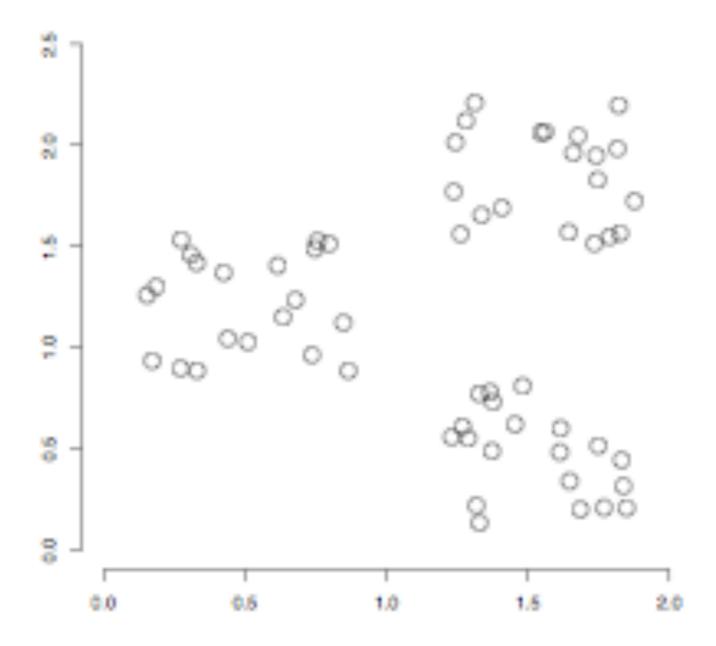

Propose an algorithm that might be able to do this!

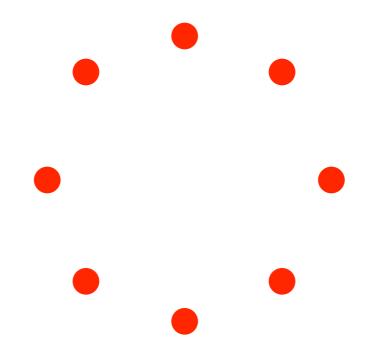

- Input: number of desired clusters K
- Output: assignment of documents to K clusters
- Algorithm:
 - randomly select K documents (seeds)
 - assign each remaining document to its nearest seed

• Could this work?

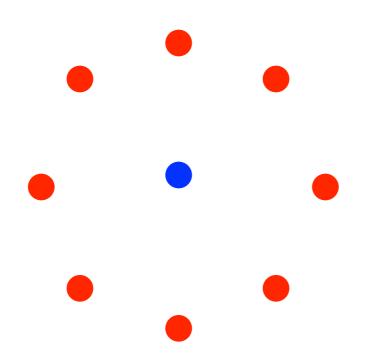

K-Means Clustering

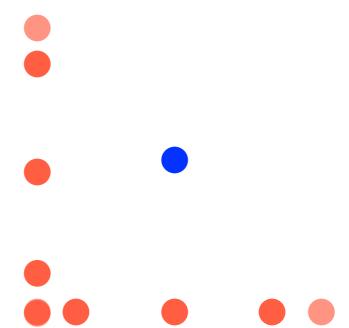

- The key to understanding K-means clustering is to understand the idea of a cluster centroid
- Given a cluster, you can think of its centroid as a point (or vector) that corresponds to its "center of mass"

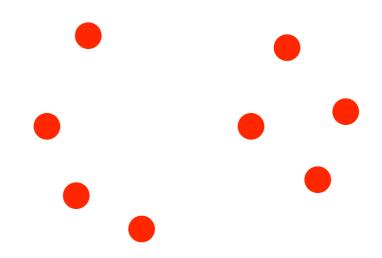

- The key to understanding K-means clustering is to understand the idea of a cluster centroid

K-means Clustering cluster centroid

• For each dimension i, set:

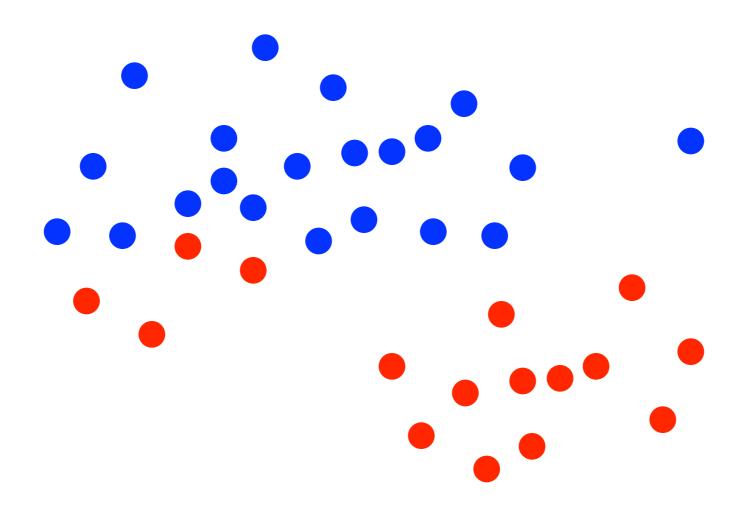

$$c_i = \frac{1}{|C|} \sum_{d \in C} d_i$$

- Input: number of desired clusters K
- Output: assignment of documents to K clusters
- Algorithm:
 - Step 1: randomly select K documents (seeds)
 - Step 2: assign each document to its nearest seed
 - Step 3: compute all K cluster centroids
 - Step 4: re-assign each document to its nearest centroid
 - Step 5: re-compute all K cluster centroids
 - Step 6: repeat steps 4 and 5 until terminating condition

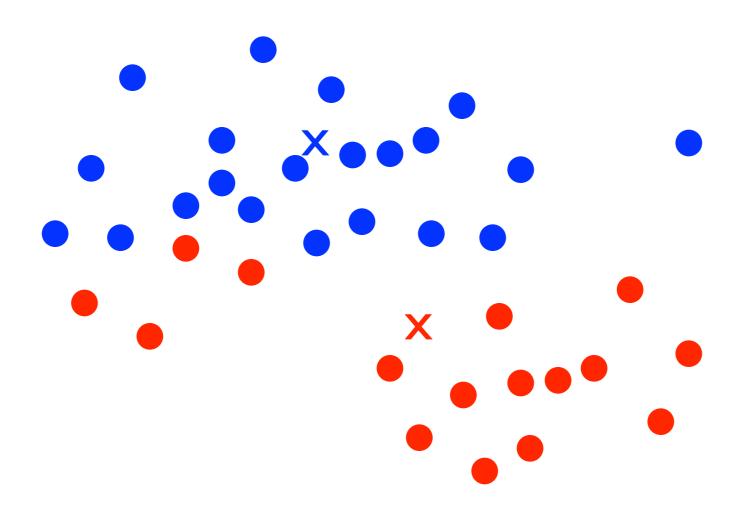

• Step 1: randomly select K documents (seeds)

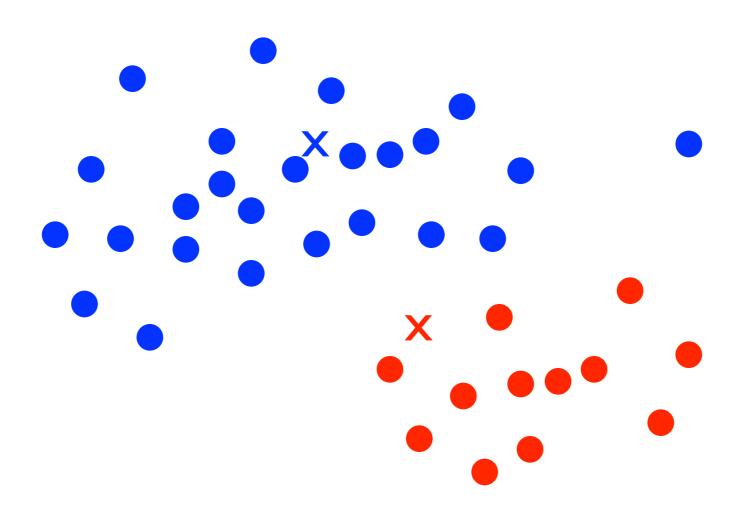

Step 2: assign each document to its nearest seed

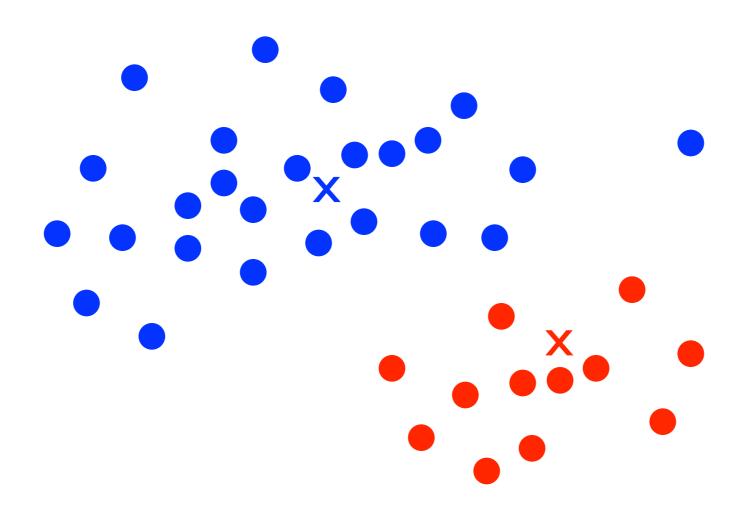

• Step 3: compute all K cluster centroids

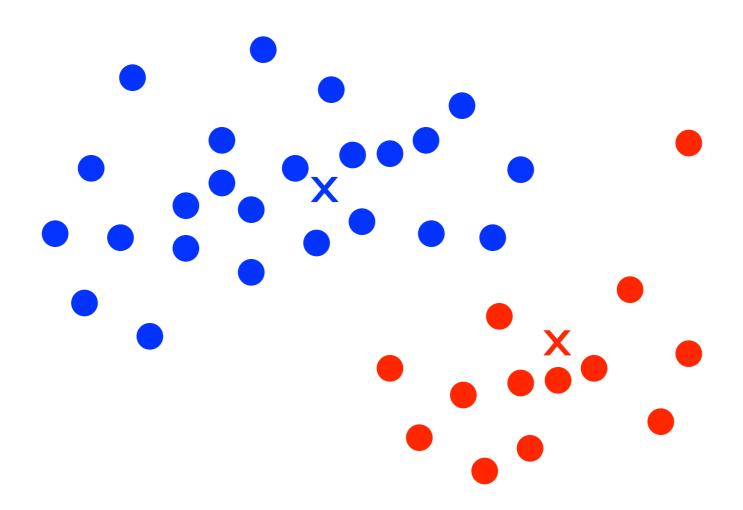

Step 4: re-assign each document to its nearest centroid

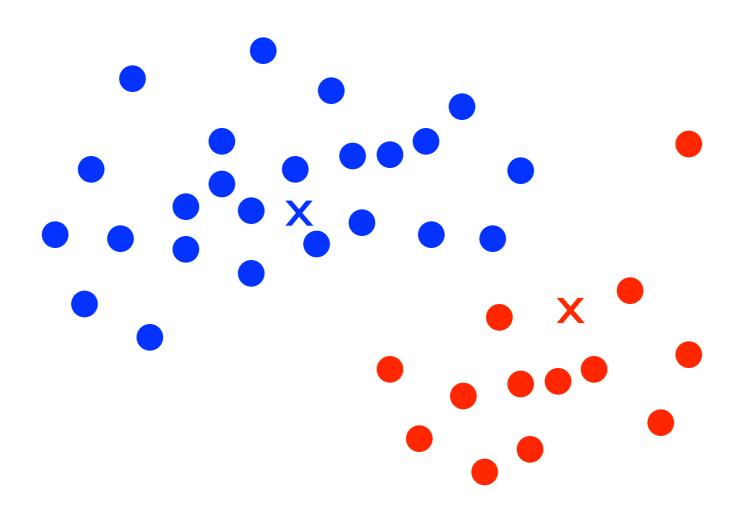

• Step 4: re-compute all K cluster centroids

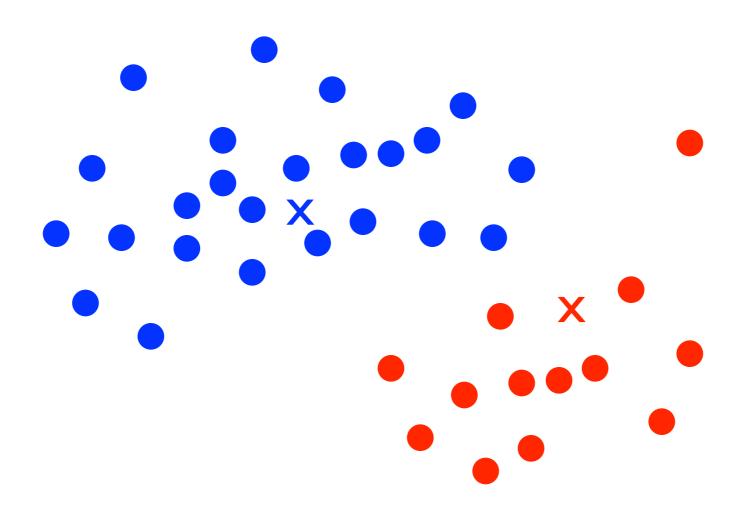

Step 5: re-assign each document to its nearest centroid

• Step 4: re-compute all K cluster centroids

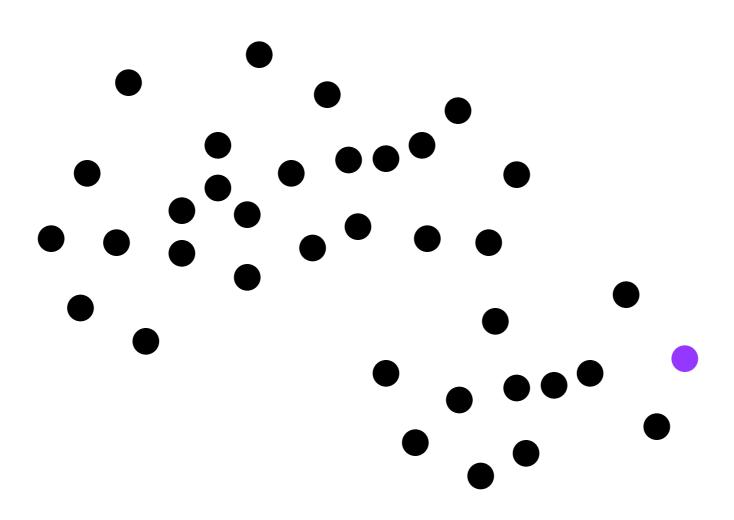

Step 5: re-assign each document to its nearest centroid

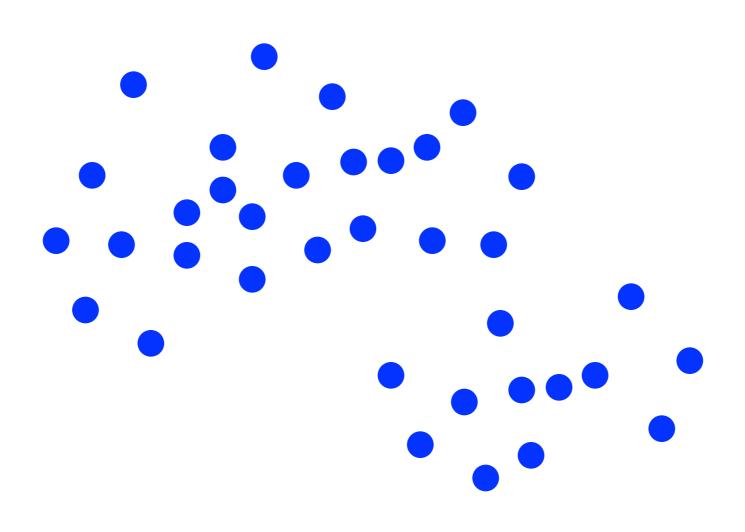

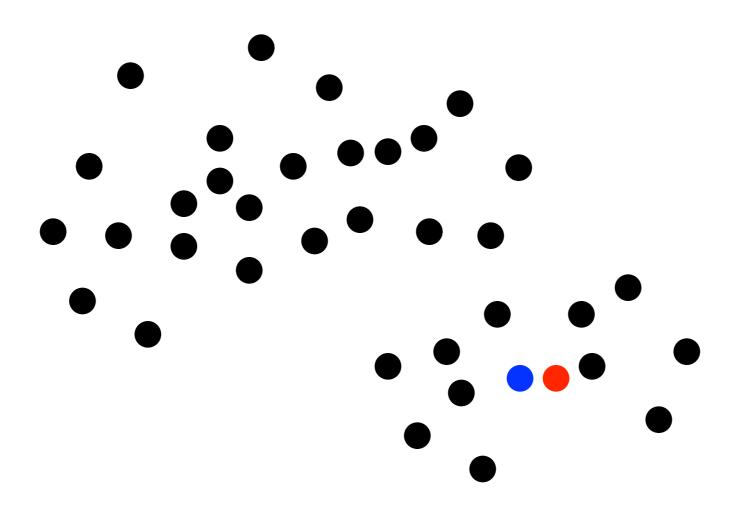

- Input: number of desired clusters K
- Output: assignment of documents to K clusters
- Algorithm:
 - Step 1: randomly select K documents (seeds)
 - Step 2: assign each document to its nearest seed
 - Step 3: compute all K cluster centroids
 - Step 4: re-assign each document to its nearest centroid
 - Step 5: re-compute all K cluster centroids
 - Step 6: repeat steps 4 and 5 until terminating condition

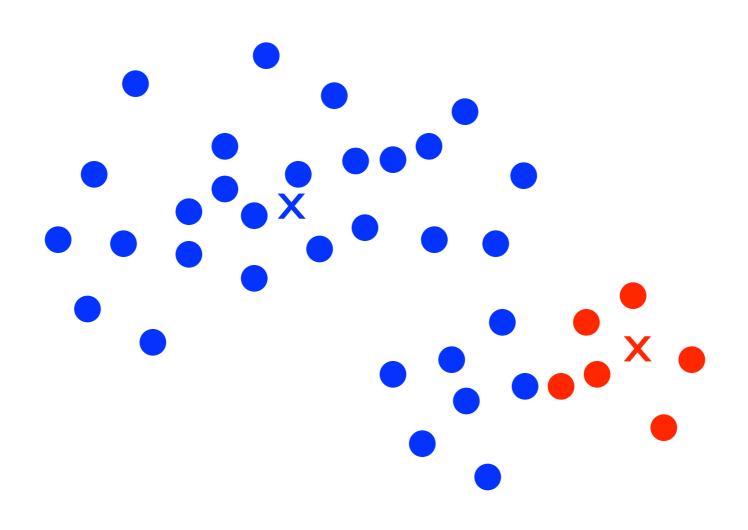

K-means Clustering potential drawback

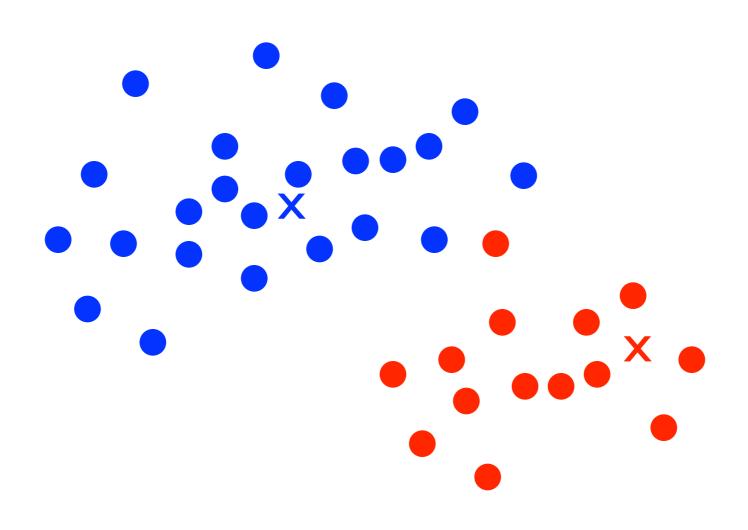

- The quality of the output clustering depends on the choice of K and on the initial seeds
- In many cases, the choice of K is pre-determined by the application
 - Search engine results clustering: grouping search engine results by topic
 - Collection clustering: grouping documents by topic to support navigation and exploration
- Later we'll see ways of setting K dynamically

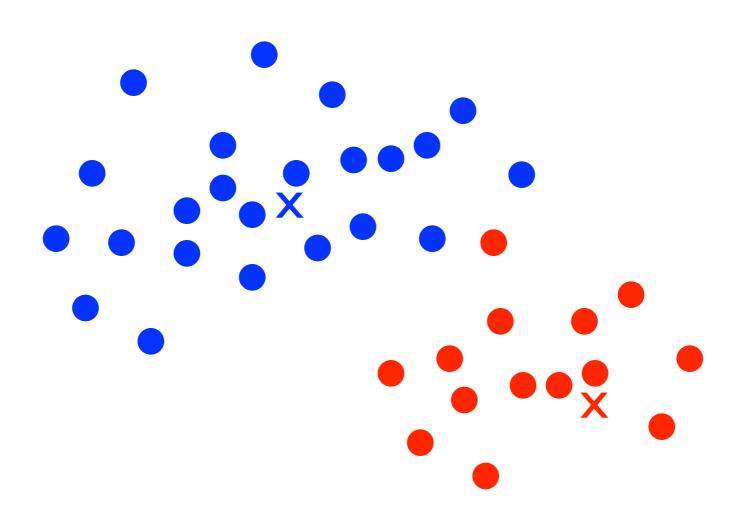

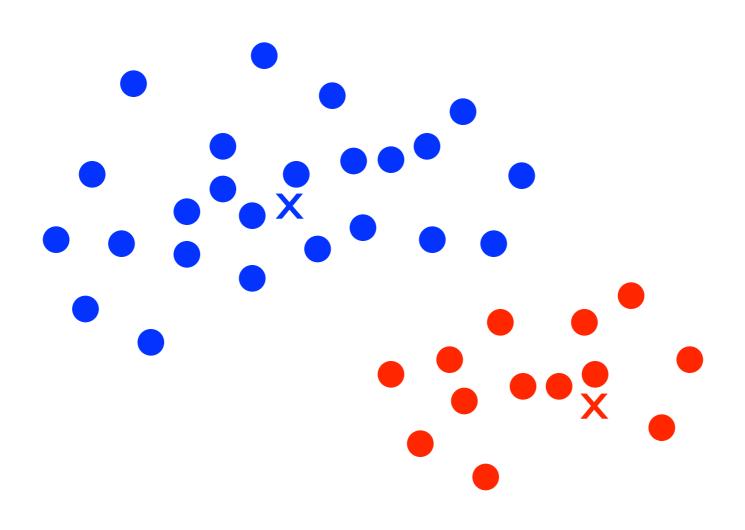

- It's difficult to know which seeds will yield a highquality clustering
- However, it's usually a good idea to avoid seeds that are outliers
- How would you detect outliers?

K-means Clustering clustering evaluation

- What does it mean for a clustering to be high quality anyway?
- What is the goal of clustering again?

K-means Clustering internal evaluation

- In theory, a good clustering should have:
 - Similar documents in the same clusters
 - Different documents in different clusters

K-means Clustering internal evaluation

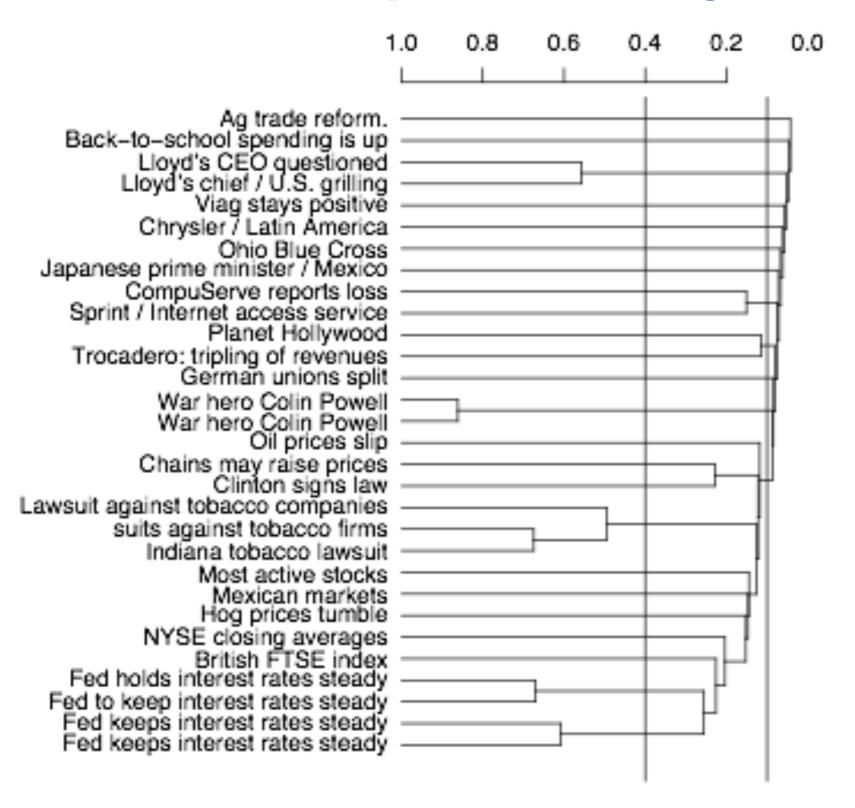

Clustering — Setween all pairs of documents in documents in documents in the same cluster

K-means Clustering improved k-means

 Given a set of documents and a value K, run Kmeans clustering N times and keep the clustering that produces the greatest difference between the intercluster distance and the intra-cluster distance

Bottom-up Agglomerative Clustering

- While K-means requires setting K, bottom-up clustering groups the data in a hierarchical fashion
- We can then set K after the clustering is done or use a distance threshold to set K dynamically (more on this later)

- Input: data
- Output: cluster hierarchy
- Algorithm:
 - Step 1: consider every document its own cluster
 - Step 2: compute the distance between all cluster pairs
 - Step 3: merge/combine the nearest two clusters into one
 - Step 4: repeat steps 2 and 3 until every document is in one cluster

- Input: data
- Output: cluster hierarchy
- Algorithm:
 - Step 1: consider every document its own cluster
 - Step 2: compute the distance between all cluster pairs
 - Step 3: merge/combine the nearest two clusters into one
 - Step 4: repeat steps 2 and 3 until every document is in one cluster

- Computing the distance between two clusters
- Single-Link: the distance between the two nearest documents
- Complete-Link: the distance between the two documents that are farthest apart
- Average-Link: the average distance between all document pairs in the two different clusters
 - this is equivalent to using the distance between the two cluster centroids

• Step 1: consider each document its own cluster

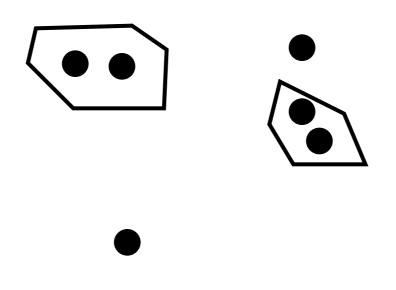

- Step 2: compute the distance between all cluster pairs
- Step 3: merge/combine the nearest two clusters into one

70

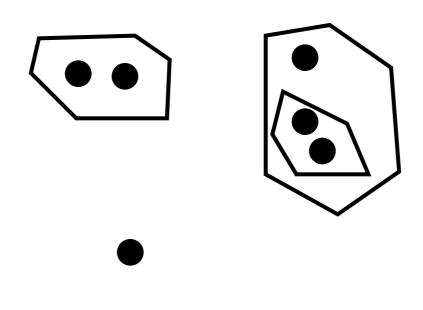

- Step 2: compute the distance between all cluster pairs
- Step 3: merge/combine the nearest two clusters into one

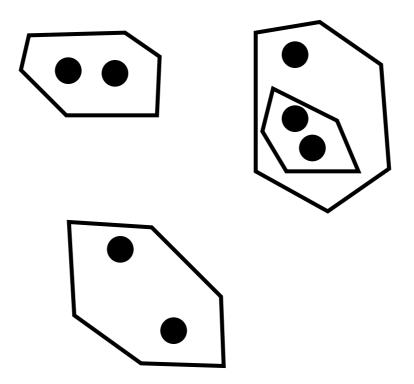

- Step 2: compute the distance between all cluster pairs
- Step 3: merge/combine the nearest two clusters into one

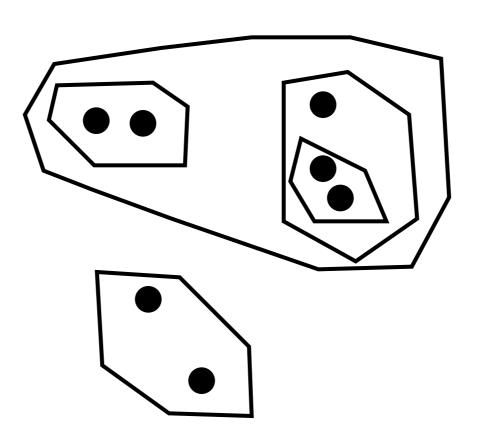

- Step 2: compute the distance between all cluster pairs
- Step 3: merge/combine the nearest two clusters into one

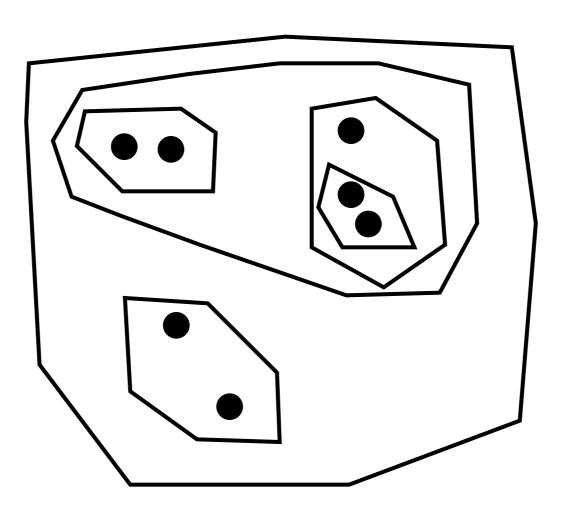

- Step 2: compute the distance between all cluster pairs
- Step 3: merge/combine the nearest two clusters into one

- Step 2: compute the distance between all cluster pairs
- Step 3: merge/combine the nearest two clusters into one

- Step 2: compute the distance between all cluster pairs
- Step 3: merge/combine the nearest two clusters into one

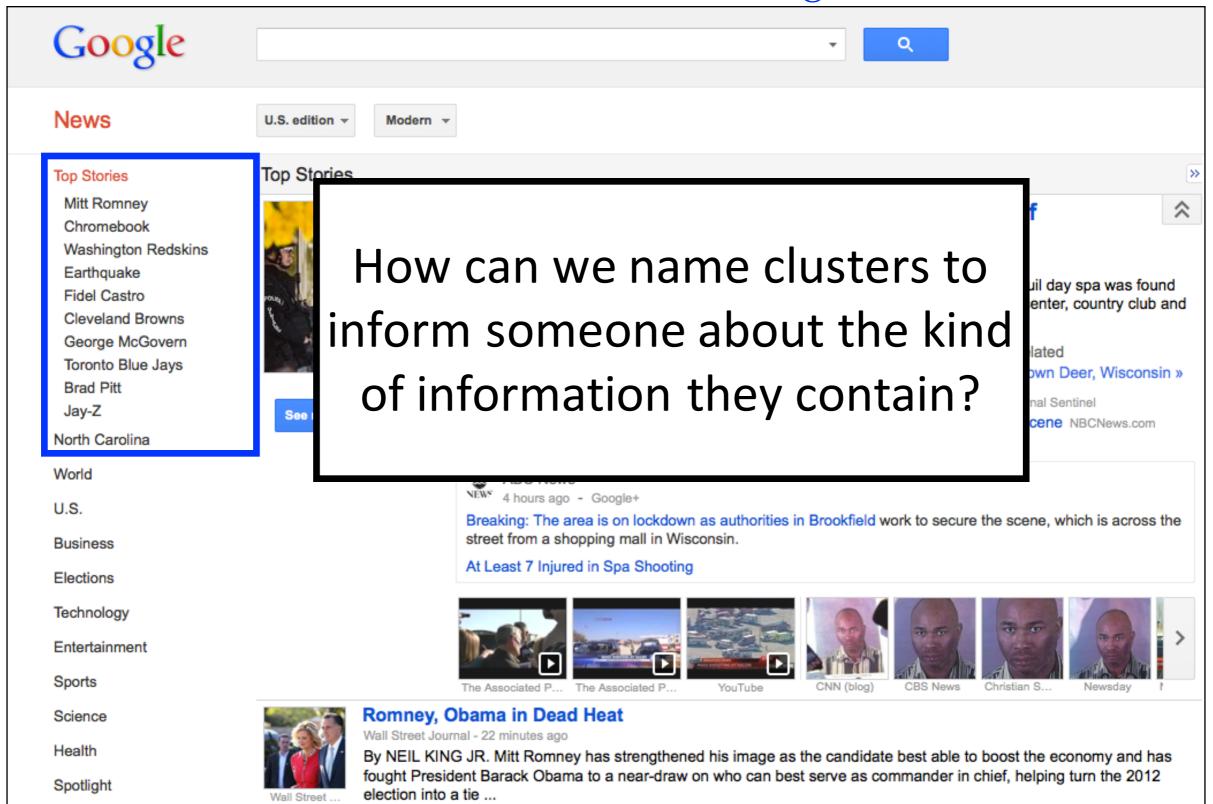

Bottom-up Clustering

- Setting K dynamically
- Instead of setting K, we could set a distance threshold T
- Stop merging/combining clusters when the distance between the two nearest clusters > T
- Using a distance threshold can help prevent "concept drift" (especially with single-link clustering)
 - text mining --> inls 613 --> unc --> basketball

Labeling Clusters

Clustering Applications

collection clustering

Labeling Clusters A simple solution

- Construct a vocabulary of terms and/or phrases (n-grams) that are frequent in the data
- Assign each cluster the term(s) or phrase(s) with the highest mutual information

$$MI(w,c) = \log\left(\frac{P(w,c)}{P(w)P(c)}\right)$$

- P(w,c): the probability that a document contains word w and belongs to cluster c
- P(w): the probability that word w occurs in a document from any cluster
- P(c): the probability that a document belongs to cluster c

$$MI(w,c) = \log \left(\frac{P(w,c)}{P(w)P(c)}\right)$$

- If P(w,c) = P(w) P(c), it means that the word w is independent of cluster c
- If P(w,c) > P(w) P(c), it means that the word w is not independent of of cluster c

Every document falls under one of these quadrants

belongs to cluster C	does not
	belong to
	cluster C

total # of instances N = a+b+c+d

$$P(w,c) = ???$$

$$P(c) = ???$$

$$P(w) = ???$$

$$P(w) = ??'$$

contains

word W

$$MI(w,c) = \log\left(\frac{P(w,c)}{P(w)P(c)}\right)$$

Every document falls under one of these quadrants

belongs to cluster c does not belong to cluster c

total # of instances N = a + b + c + d

P(w,c) = a / N

P(c) = (a + c) / N

P(w) = (a + b) / N

 $MI(w,c) = \log \left(\frac{P(w,c)}{P(w)P(c)}\right)$

contains word w

does not contains word w

a	b
C	d

Summary

- Clustering: grouping similar documents (or instances) into subsets
- Exploratory analysis: the goal is to discover common and uncommon properties of the data
- K-means and Agglomerative Bottom-up Clustering (there are many, many others)
- Labeling clusters
